

Individual Submission 2

Cole Dorman

Contributions:

TelemetryListenerComponent

Created a new abstract ActorComponent that can be extended via C++ or blueprint, allowing for proper decoupling. Added a system to auto sample position based on a configurable exposed tick value. I also added BlueprintNativeEvent hooks so subclasses can override. One of the biggest reasons this mattered is it had set out and successfully accomplished the core issue I had found in the first submission (The tight coupling and how messy the eventgraph was). It also prevents me needing to check out the player character as often. The refactor was kinda painful to do since it had become somewhat intertwined to p4v, but I did get it done which I was feeling very elated about given it had been plaguing me for a while.

Room logging

To prepare for the art team's implementation of PLA based rooms, I had created an entire system that allows me to hook into unreal engines leveloader and cache the PLA's in the scene, which I can use later to see if the player is within their bounds. Currently this is a proof of concept since the art team had missed their side. I had also been informed we are changing to PLI (Due to Kevin mentioned PLI's are industry standard, to jayrald) which throws a wrench into things but I am hoping they should be similar enough I don't need to reinvent anything. The primary reason for this to be added is since we can derive room specific information and determine lots of immediately actionable data. I am happy with the results nonetheless as it worked properly, despite nothing else being in place on the other sides. Also to stress it more, so I am clear no intervention is needed, I have spoke with the artists already, and we are in contact. I would only ask that if

other decisions are made that directly impact my work, such as switching from PLI's to another way of packaging assets I am informed.

Streamlined Marimo visualizations & git repo

Improved the automatic launch syncing for vscode, added the current schema to allow for editor awareness & future validation. Did a massive find-replace to change future and old event logs, "framecount" → "event_order". This was since framecount was a mistake and not actually logging framecount, but could be used for definite event ordering, framecount was then added after. I had also added extra visualizations such as health, damage and most common damage dealers, which we can derive actionable insights from as a team. I also did some learning of Altair which is another powerful visualization tool, it took me quite a bit to get the hang of it, but I am far more comfortable now and I feel I can apply it for future visualizations if we need. Effectively improving the variety of tools available to me. All of these changes directly improve my workflow to allow faster iterations and testing of new features. This allows me to be flexible and match the team's playtest speed. It also feels really good to be able to further learn the tools I have at my disposal.
